The mathematical theory of elasticity under equilibrium consists in this, that knowing the action of external forces (loads) and the so-called boundary conditions, it is possible to determine the values, at each point of the body, of the components of the stress and the deformation, as well as the components u_x, u_y, u_z of the displacement vector at each part of the body, $i \dots$

The elastic deformation of a solid is a reversible process, when the applied stress is removed the solid returns to its original state.

Elasticity is also discussed mathematical modeling to denote reversibly changeable boundaries. Plasticity. Plasticity is a concept which is connected with the plastic deformation.

In physics and materials science, elasticity is the ability of a body to resist a distorting influence and to return to its original size and shape when that influence or force is removed. Solid objects will deform when adequate loads are applied to them; if the material is elastic, the object will return to its initial shape and size after removal. This is in contrast to plasticity, in which the object fails to do so and instead remains in its deformed state. The physical reasons for elastic be
